Ionic Bonds: Formed when electrons are transferred from metal to non-metal, resulting in positive and negative ions held together by electrostatic forces.

Covalent Bonds: Occur when atoms share electron pairs, common in non-metals.

Metallic Bonds: Involve a 'sea' of delocalized electrons shared among metal atoms, leading to properties like conductivity.

Molecular Structures and Lewis Dot Diagrams

Lewis structures depict valence electrons and bonding patterns. They help predict molecular shapes when combined with VSEPR theory.

VSEPR Theory and Molecular Geometry

Valence Shell Electron Pair Repulsion (VSEPR) theory is instrumental in modeling molecular shapes based on electron pairs.

Principles of VSEPR

Electron pairs, both bonding and lone pairs, repel each other and arrange themselves to minimize repulsion. The shape of the molecule is determined by the number of bonding pairs and lone pairs around the central atom.

Common Molecular Geometries

Linear: 2 electron groups (e.g., CO_2)

Trigonal Planar: 3 electron groups (e.g., BF_3)

Tetrahedral: 4 electron groups (e.g., CH_4)

Trigonal Pyramidal: 3 bonding pairs + 1 lone pair (e.g., NH_3)

Sample Questions and Model Answers

Question 1: Describe how the Rutherford gold foil experiment contributed to the development of the nuclear model of the atom.

Answer: The Rutherford gold foil experiment was pivotal in transforming atomic models. In this experiment, alpha particles were directed at a thin gold foil. Most particles passed through with minimal deflection, but some were deflected at large angles, and a few even bounced back. This observation contradicted the plum pudding model, which envisioned a diffuse positive charge. Rutherford interpreted these results to mean that the positive charge and most of the atom's mass are concentrated in a small, dense nucleus at the center. The electrons orbit this nucleus, explaining why most alpha particles passed through unobstructed, but some experienced significant deflection due to close encounters with the nucleus. This experiment led to the nuclear model, which remains fundamental in modern atomic theory.

Question 2: Using the ideal gas law, calculate the volume occupied by 2 mol of oxygen gas (O₂) at 25°C and 1 atm pressure.

Answer: Given data: Moles, $n = 2 \text{ mol}$ Temperature, $T = 25^\circ\text{C} = 298 \text{ K}$ Pressure, $P = 1 \text{ atm}$ Gas constant, $R = 0.0821 \text{ L}\cdot\text{atm}/(\text{mol}\cdot\text{K})$

Applying the ideal gas law: $PV = nRT$

Calculations: $V = (nRT) / P = (2 \text{ mol} \cdot 0.0821 \text{ L}\cdot\text{atm}/(\text{mol}\cdot\text{K}) \cdot 298 \text{ K}) / 1 \text{ atm}$

$V = (2 \cdot 0.0821 \cdot 298) / 1$

$V = 48.9 \text{ L}$

Thus, 2 mol of oxygen at 25°C and 1 atm occupies approximately 48.9 L

liters. Effective Study Tips for Unit 9 2 Modeling Chemistry Master Key Diagrams: Practice drawing Lewis structures, orbital diagrams, and molecular geometries.
